Volume 22 Issue 5
DyC selectively dynamically compiles programs during their execution, utilizing the run-time-computed values of variables and data structures to apply optimizations that are based on partial evaluation. The dynamic optimizations are preplanned at static compile time in order to reduce their run-time cost; we call this staging. DyC's staged optimizations include (1) an advanced binding-time analysis that supports polyvariant specialization (enabling both single-way and multi ...

ACM Transactions on Programming Languages and Systems (TOPLAS) March 1995 Volume 17 Issue 2

Proceedings of the ACM 1999 conference on Java Grande June 1999

Compiling for distributed-memory machines has been a very active research area in recent years. Much of this work has concentrated on programs that use arrays as their primary data structures. To date, little work has been done to address the problem of supporting programs that use pointer-based dynamic data structures. The techniques developed for supporting SPMD execution of array-based programs rely on the fact that arrays are statically defined and directly addressable. Recursive data s ...

12 Separation constraint partitioning: a new algorithm for partitioning non-strict programs into sequential threads

Klaus E. Schauser , David E. Culler , Seth C. Goldstein

Proceedings of the 22nd ACM SIGPLAN-SIGACT symposium on Principles of programming languages January 1995

In this paper we present substantially improved thread partitioning algorithms for modern implicitly parallel languages. We present a new block partitioning algorithm, separation constraint partitioning, which is both more powerful and more flexible than previous algorithms. Our algorithm is guaranteed to derive maximal threads. We present a theoretical framework for proving the correctness of our partitioning approach, and we show how separation constraint partitioning mak ...

13 Region-based memory management in cyclone

Volume 37 Issue 5

Cyclone is a type-safe programming language derived from C. The primary design goal of Cyclone is to let programmers control data representation and memory management without sacrificing type-safety. In this paper, we focus on the region-based memory management of Cyclone and its static typing discipline. The design incorporates several advancements, including support for region subtyping and a coherent integration with stack allocation and a garbage collector. To support separate compilation, C ...

14 Incremental partial evaluation: the key to high performance, modularity and

Volume 37 Issue 3

Traditional compilers compile and optimize files separately, making worst-case assumptions about the program context in which a file is to be linked. More aggressive compilation architectures perform cross-file interprocedural or whole-program analyses, potentially producing much faster programs but substantially increasing the cost of compilation. Even more radical are systems that perform all compilation and optimization at run-time: such systems can optimize programs based on run-time program ...

16 Formalizing the safety of Java, the Java virtual machine, and Java card

94%

Pieter H. Hartel , Luc Moreau

ACM Computing Surveys (CSUR) December 2001

Volume 33 Issue 4

We review the existing literature on Java safety, emphasizing formal approaches, and the impact of Java safety on small footprint devices such as smartcards. The conclusion is that although a lot of good work has been done, a more concerted effort is needed to build a coherent set of machine-readable formal models of the whole of Java and its implementation. This is a formidable task but we believe it is essential to build trust in Java safety, and thence to achieve ITSEC level 6 or Common Crite ...
